

Software Engineering Workshop – Week 4

Here are some suggestions for tasks to be getting on with:

- Apply Systemic Textual Analysis exercise for your projects requirements. Can you identify anything that is missing?
- You could repeat the Viewpoint Analysis exercise for your project requirements. Remember that the idea is to capture the requirements as fully as possible, to categorize them, group them and produce a hierarchy that shows the relationships between the functional requirements. Your diagram should also show how the non-functional requirements relate to the functional ones.
- Once you have analysed the requirements using the methods above, apply the MoSCoW method.
- Check whether your revised set of requirements matches the characteristics of good ones. Produce a table that acts as a check list for this.
- If you have identified any new non-functional system or performance requirements, think about how you would go about measuring them. This is key to good testing.
- Complete an FFD, or a series of hierarchical FFD diagrams for the system you are developing for your project.
- Have a general project meeting to discuss your progress, and which requirements methods might be most effective for your product.
